Long-Term Trends in Ecological Systems: An Introduction to Cross-Site Comparisons and Relevance to Global Change Studies

D.P.C. Peters, C.M. Laney, A.E. Lugo, S.L. Collins, C.T. Driscoll, P.M. Groffman, J.M. Grove, A.K. Knapp, T.K. Kratz, M.D. Ohman, R.B. Waide, and J. Yao

Earth's environment is changing in many ways at local, regional, and global scales. Dramatic changes in climate, land cover, and habitat availability have occurred over the past several centuries. Long-term data (exceeding 10 years) are needed to assess the rate and direction of change, to distinguish directional trends in these changes (such as persistent increases or decreases) from short-term variability (of multiyear cycles, for instance), and to forecast environmental conditions in the future. As an indication of global changes, for example, carbon dioxide in Earth's atmosphere has been increasing since 1958 at Mauna Loa in Hawaii (Keeling et al. 2001, 2005). Although this "Keeling Curve" fluctuates from year to year, global atmospheric concentrations of carbon dioxide (CO₂) are clearly rising (figure 1-1) (Keeling et al. 2001, 2005). This global increase in CO₂ is likely responsible for the observed rise in global average temperatures and

Figure 1-1. Monthly average atmospheric carbon dioxide concentration (CO₂ in parts per million in the mole fraction) through time at Mauna Loa Observatory, Hawaii (19.5°N, 155.6°W) (Keeling et al. 2001, 2005). (Data from http://scrippsco2.ucsd.edu/data/atmospheric_co2.html.)

acidification of the ocean, which lead to coral bleaching and loss of coral reefs (IPCC 2007). The spread of invasive species and of infectious diseases constitutes additional drivers of global change that have significant ecological and economic consequences. Finally, human populations are increasing in numbers, changing in economic status, and moving around the country, resulting in uneven spatial distribution of ecological impacts (Grimm et al. 2008a, 2008b).

Only by using long-term data can these changes and their effects be detected and monitored. These changes have important consequences for the services that ecological systems provide to humans, such as clean air and water and food, fiber, and energy (Daily 1997, Palmer et al. 2004, 2005). Thus, long-term data are vital for assessing status and trends of a variety of components of ecological systems and for predicting and managing future environmental conditions needed for a sustainable Earth (Magnuson 1990, Moran et al. 2008, Janzen 2009).

Fortunately, ecological research in the United States has a long history, dating from the 1800s. Sites were initially established by United States Department of Agriculture (USDA), Forest Service (FS) to preserve forests in the face of widespread fires and increasing human population density. Rangeland sites as part of USDA, Agricultural Research Service (ARS) were established to limit land degradation from overgrazing by livestock, particularly during periods of severe drought. In many cases, the initial research was observation based and focused on vegetation properties, such as plant cover.

Through time, a systems approach has become prevalent among ecologists such that many components of a system are studied, including soil properties and plant, animal, and microbial populations and communities, as well as nutrient cycling (Golley 1993). Linking ecological responses with environmental drivers was made possible initially with the National Weather Service's network of sites, which started collecting meteorological data in 1870 (<http://www.nws.noaa.gov/>), and more recently with site-based weather stations that are part of a large network of sites in the United States (<http://www.ncdc.noaa.gov>) and globally (<http://www.wmo.int>). Other drivers include streamflow, which has been monitored at some sites for over 100 years by the U.S. Geological Survey (<http://waterdata.usgs.gov>), and the census of human demography and economy by the U.S. Census Bureau since 1830 (<http://www.census.gov>).

Long-Term Trends in Ecological Systems:

With the advent of computational resources in the 1960s, long-term data collection became more practical because large quantities of information could be collected, aggregated, managed, stored, analyzed, and made accessible to others. Advances in information management and software development allowed these vast amounts and kinds of data to be accessible by current and future users (Michener and Brunt 2000). Measurement technology and coordinating activities also improved. For example, sites began monitoring precipitation chemistry in 1978 through the National Atmospheric Deposition Program (<http://www.nadp.isws.illinois.edu/>). As technology advanced into the 21st Century, long-term research and information systems design have become more sophisticated (Baker et al. 2000, Hobbie et al. 2003). Small, plot-based experiments have been complemented with patch- and landscape-scale extrapolations and manipulations that can be studied over long periods (Cottingham and Carpenter 1998, Carpenter 2002). Aerial photographs obtained by the U.S. Government starting in the 1930s and updated every decade have been combined since the 1970s with remotely sensed satellite images. Analyses of these images through time and space using large computational resources and new algorithms have shown fine- to broad-scale dynamics. More recent advances include wireless technology that allows data to be collected remotely and simultaneously for many locations (Porter et al. 2005, Collins et al. 2006). Theoretical, statistical, and simulation models have been developed that allow the synthesis of different sources and kinds of data for many systems, provide new insights into dynamics, guide development of new studies, and improve prediction about future dynamics for many sites and ecosystem types (for example, Parton et al. 1993, Rastetter et al. 2003).

Networks of long-term research sites and observation systems, such as the Long Term Ecological Research Network (LTER), have become increasingly important as our understanding expands about the complexities and interconnections among components of Earth as a system (Gosz 1999, Peters et al. 2008). These networks often collect similar types of data that can be used to compare sites, both within the same biome (such as multiple grassland sites) and among different biomes (for example: deserts, grasslands, and forests) (Hobbie et al. 2003). Cross-site comparisons are valuable in determining generalities in ecological responses to different drivers and in examining variation in responses to the same driver (Hobbie 2003).

However, multisite comparative studies have not reached their full potential because of limitations in our understanding of data system design and of the data themselves—their types, organization, management, and practices. In most cases, the data have been used primarily by the scientists who collected the data or their close collaborators because of issues relating to content, format, exchange, contextualization, and standards. The reasons for these data issues and resulting limitations on their use include that data—

- are collected to address site- or system-specific questions (often using site-designed methodologies),
- are recorded in unique local or proprietary formats,
- are available only directly from individual researchers or from research site web pages,
- have limited metadata, the descriptive information required to understand the sampling design and repeat the sampling methods, and
- do not include cross-references because of a lack of local or domain level vocabularies and standards.

In many cases, the data have been published either as individual studies or as part of site synthesis volumes (see <http://www.oup.com/us/catalog/general/series/TheLongTermEcologicalResearchNet> for an example). In cases in which synthetic papers were published to address multiple site questions (for example, Magnuson et al. 1991, Kratz et al. 1995, Riera et al. 1998, 2006; Knapp and Smith 2001, Parton et al. 2007), the data were primarily obtained directly from scientists.

The amount of data available remotely has increased with the World Wide Web; however, these data are typically in an “original” form—the way in which the data were recorded and delivered. Fully comprehending the data is often a complex undertaking because there is detailed information specific to the sampling design to consider, such as transect number, quadrat number, day of sampling, and sample number. Users often require “derived” data products that are aggregations of the originally submitted data reconfigured to allow cross-site comparisons. For example, plant production of a community can be obtained by collecting biomass samples by individual plants in a large number of small quadrats (1 m²) located along transects designed to capture the spatial variability in a system. Total biomass of all plants (g/m²) collected at multiple times during the year is needed to determine the change in biomass through time as an estimate of net primary production (g/m²/y). It is the annual primary production of an ecosystem that is most commonly compared across sites rather than the complex original data. Precipitation

A Basis for Understanding Responses to Global Change

provides another example of the need for derived data when comparing sites. Precipitation is collected daily, yet it is monthly or annual aggregations of precipitation that are the most useful for comparing sites.

As our ability to collect data over broad areas and long time periods increases, and our need to understand multisite dynamics increases, it will be increasingly important that these data are well documented, easy to access and use, and stored and maintained in common formats for use by future generations (chapter 16). This report and its accompanying web page (<http://www.ecotrends.info>) represent initial steps in the process of understanding data requirements and developing standards for long-term datasets for cross-site studies. Further, our work provides a foundation for the inclusion of additional data and sites in the dynamic online component of the project.

Purpose and Audience

The intent of this book is twofold—

- Illustrate the importance of long-term data in comparing dynamics across sites and in providing the context for understanding ecological dynamics of relevance to society (chapters 3-10), and
- Present long-term ecological data from different sources and a large number of sites in a common format that is easily understood and used by a broad audience (chapters 11-14).

The writing style, background information, and photos allow users across a range of expertise to grasp and access this information. A perusal of the figures for a specific site or region can lead to the discovery of interesting patterns, such as “Air temperature is increasing through time for a site in my area, yet precipitation is decreasing.” Or “Air temperature is decreasing in my area, yet it is increasing in many other parts of the country.” In this sense, the book is analogous to an amateur astronomer’s telescope: It provides access to a universe of long-term data that were previously available only to a small group of scientists.

Second, the large number of detailed graphs showing long-term data for many sites serves as a key reference for students, educators, and scientists interested in detailed patterns in both global change drivers and ecosystem responses. Because these data can be downloaded from our website (<http://www.ecotrends>

info), more detailed analyses can be conducted by individual users.

Finally, for most of these sites, data are still being collected. This book, then, serves as an important benchmark of historical patterns that can be compared with future observations as Earth continues to change. Because data are frequently interpreted differently by different people, we present the data and trend lines with limited explanation as a prompt for users to provide their own interpretations.

Practical Applications

This book has practical applications that add to its usefulness and relevance. Land managers can use the data and figures to provide a basis for interpreting local patterns in vegetation and soils observed and managed on the ground. These patterns may be short term and can be misleading without the long-term context provided by historical data. In some cases, a short-term trend can be confirmed by long-term data, demonstrating that a change in management policy may be required. In other cases, long-term data are needed to determine whether short-term changes, such as periodic drought, are cyclic. This information can be used to justify a local, short-term management action rather than a broader scale or long-term change in policy. In addition, climate and other drivers are themselves changing and modifying these patterns in potentially unique ways. Depicting long-term trends in both drivers and ecological responses can be extremely useful for interpreting the complex patterns observed by land managers (chapter 15).

The information in this book can also help explain complex issues to the general public. There is increasing public awareness of the importance of climate change to the daily lives of people, as made popular by the movie “An Inconvenient Truth” (<http://www.climatecrisis.net/>). However, it is important to differentiate climate variability from a directional change in climate. For example, extremely high air temperatures in one year that kill fruit and row crops need to be differentiated from a long-term change in temperature that shifts the growing season conditions and the locations where crops can be successfully grown. Although climate change has become a favorite topic in the popular press, long-term data on temperature and precipitation at specific sites as well as the consequences of climate change to ecosystem

dynamics are not readily available. This book presents a variety of data in forms that are accessible to people who are interested in distinguishing short-term variability from long-term trends in many different areas.

Scientists will find this book particularly useful for a number of reasons. In addition to being used to distinguish short-term variability from long-term trends, the information in this book can be used to identify gaps in knowledge that require new research (chapter 17). Equally important is the re-examination of results from previous research given the additional information provided by more years of data. For example, in southern New Mexico, the drought of the 1950s was often implicated in the demise of grasslands and shift to broad-scale shrub dominance associated with desertification (Buffington and Herbel 1965). Recent analyses of long-term quadrats show that grasses persist to the current day in some quadrats and were lost prior to the 1950s drought in others (Yao et al. 2006). Thus, the importance of the drought must be examined within the context of the long-term climate and vegetation record from 1915 (or earlier if possible) to the present.

Scientists can also use long-term data to help interpret results from short-term studies. Most experiments and observations in ecology are less than 5 years long; this study duration is related to the length of most research grants from State and Federal agencies in the United States (3-4 years). However, the implications of these results to ecosystem dynamics need to be extrapolated to decades or longer. Long-term data are often used in combination with simulation models as a reliable approach to making these extrapolations more meaningful. Federal agencies, such as the USDA Agricultural Research Service and Forest Service, provide a structure to support this type of long-term research that goes beyond competitive grants. The U.S. National Science Foundation through the Long Term Ecological Research Network and Long Term Research in Environmental Biology programs are also critical to the collection of long-term data by providing long-term funding (5-6 years) through competitive awards.

Site, Variable, and Data Selection

This book illustrates the value of long-term studies in two ways. First is the comparison of the dynamics of multiple sites by synthesizing published data in eight themes (chapters 3-10). Second is the comparison of data through time for four types of variables using graphs and maps (chapters 11-14). The focus is on data from 50 ecological research sites funded by U.S. agencies and located in North America and Antarctica, with one site in French Polynesia (figure 1-2, table 1-1). Twenty-six of the sites are individually funded by the National Science Foundation as part of the LTER Network (<http://www.lternet.edu>). Most of the remaining sites are USDA federally operated sites, either experimental forests (USFS, 14 sites) or rangelands (ARS, 7 sites); and 9 sites are affiliated with both LTER and USDA (USFS or ARS). The remaining three sites are operated by other Federal or State agencies (Loch Vale Watershed by the U.S. Geological Survey [USGS], Walker Branch Watershed by the U.S. Department of Energy, and Santa Rita Experimental Range by the University of Arizona).

These sites represent six ecosystem types common globally (arctic and alpine [including Antarctica], arid lands, coastal systems, forests, temperate grasslands and shrublands, and urban systems) (table 1-1, figure 1-3) and cover much of the range in average annual temperature and average total annual precipitation for these ecosystems (figure 1-4). The terrestrial ecosystem types broadly characterize biomes, but in many cases our ecosystem types include multiple terrestrial biomes as defined by the World Wildlife Fund (<http://www.wwf.org>) and others (table 1-2).

In some cases, our sites represent finer spatial resolution of ecosystem types than shown by biomes. For example, Niwot Ridge and Loch Vale are classified here as alpine sites based on the sampling location of most of their data in this book, although these locations are classified as coniferous forests based on the surrounding biome of larger spatial extent. In other cases, we generalize ecosystem types in order to simplify the presentation of data. For example, we distinguish forests, a large and diverse collection of sites, into western and eastern forests based only on their geographic location relative to the Mississippi

A Basis for Understanding Responses to Global Change

River. Two urban sites are distinguished in our analysis because their data collection focuses on urban effects (Baltimore Ecosystem Study and Central Arizona Phoenix); we show the biomes surrounding these cities in tables 1-1 and 1-2 to allow comparisons with similar natural ecosystems. Because coastal sites often collect data in adjoining land as well as in coastal waters, we show the land-based ecosystem type in table 1-2 to allow comparisons with similar terrestrial systems.

Variables were selected to characterize either a global change driver (climate, precipitation and stream water chemistry, human demographics) or a biotic response to drivers, primarily by plants and animals. A total of 37 variables were selected for inclusion in this book if data were available from at least 5 sites for at least 10 years and if both the original source data and the associated metadata were available (tables 1-3, 1-4, 1-5). More variables can be found on the EcoTrends website (<http://www.ecotrends.info>).

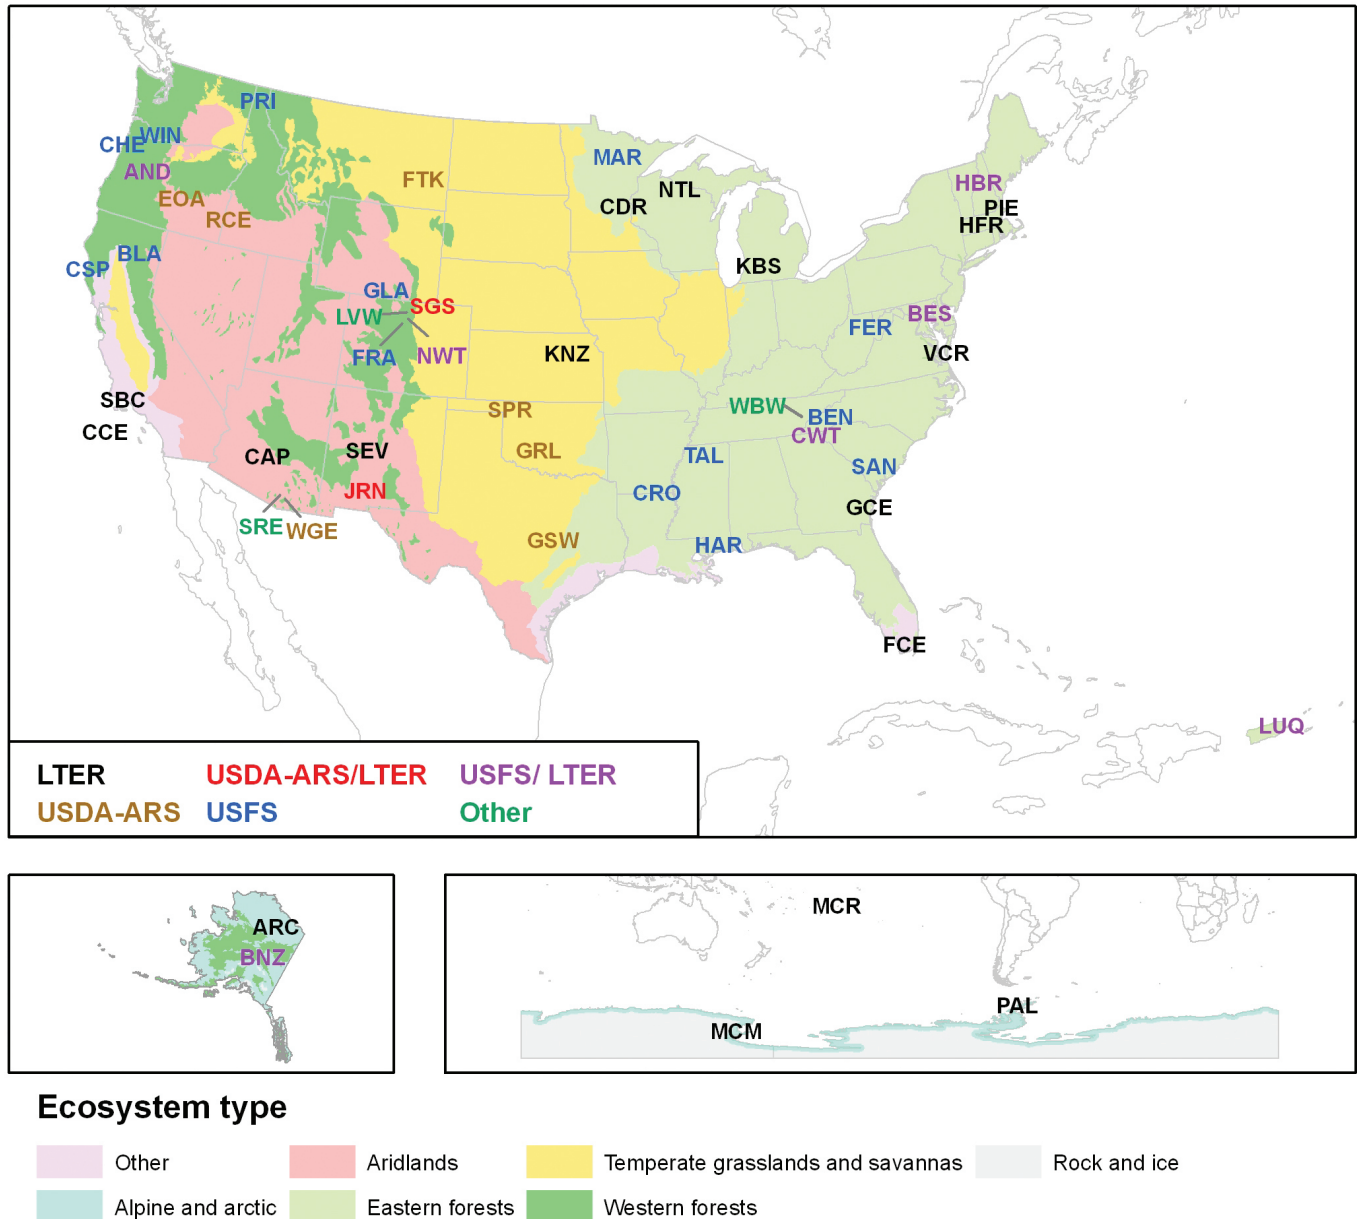

Figure 1-2. Location of sites identified by their program or funding agency, network, and agency names. Background color shows terrestrial ecosystem type used in EcoTrends from table 1-2. These colors are used throughout the book. See table 1-1 for site names and program acronyms.

Long-Term Trends in Ecological Systems:

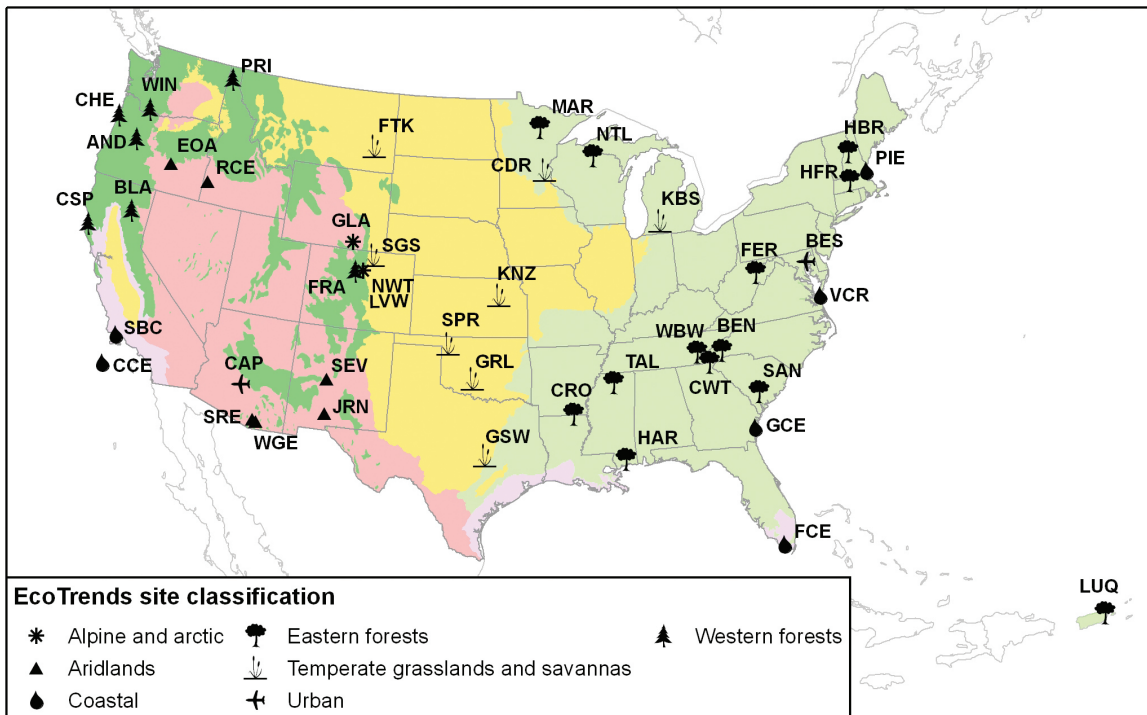

Figure 1-3. Location of sites shown by EcoTrends ecosystem type differentiated by symbols. See table 1-1 for site names.

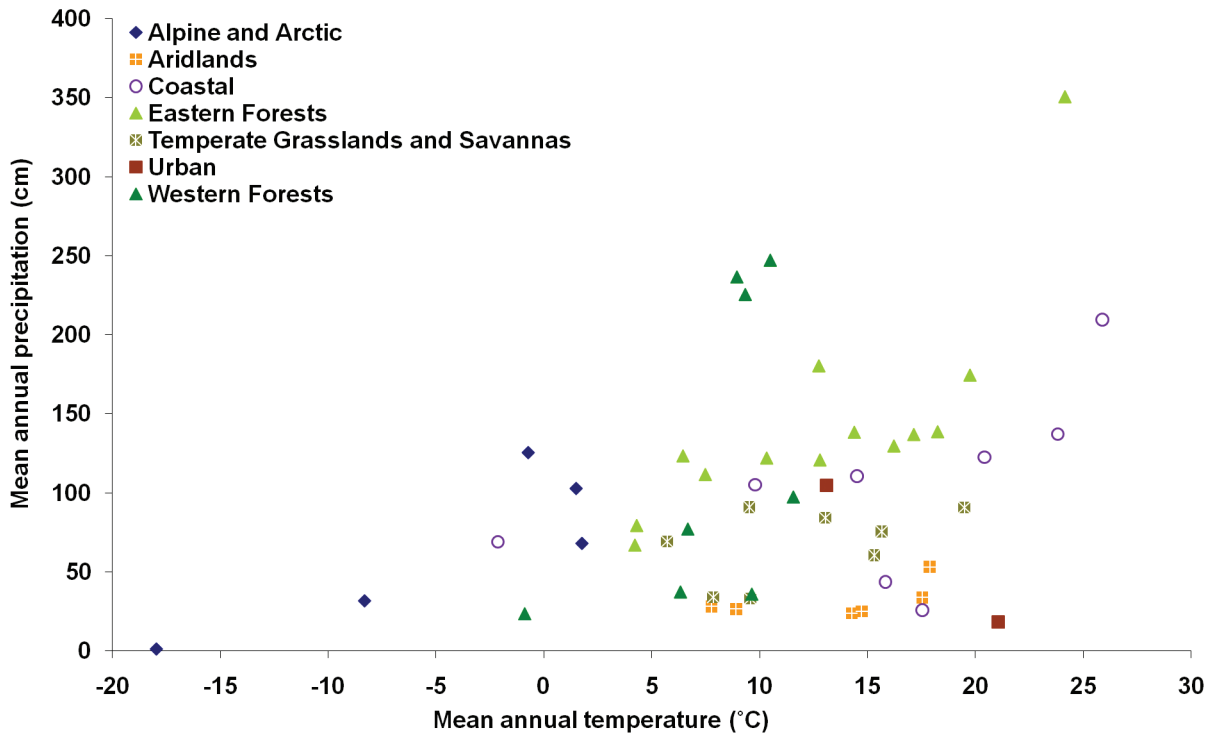

Figure 1-4. Mean annual temperature (°C) and precipitation (cm/y) of the 50 sites labeled by ecosystem type. Adjacent land area shown for coastal sites.

A Basis for Understanding Responses to Global Change

Data were obtained from one of three sources:

- Internet portals where data and metadata quality and standardization were already complete for many sites
- Individual research site web pages
- Individual researchers

Although data are often collected at more than one location within each research site, space constraints limit our analyses to a representative sampling location. We created derived data products by either averaging or summing the data from a single source, such as a weather station, or across a detailed study design to obtain one value per time step, which is typically a year or a month. Data and metadata in this book have undergone initial quality control for errors, have been formatted to a common standard, and are now available to the public from a single website (<http://www.ecotrends.info>). Users are encouraged to verify the accuracy of the data downloaded from the EcoTrends site by checking the original source of data.

Statistical Considerations

The original intent of this book (that is, to present the data in a straightforward, transparent manner to stimulate further exploration and analysis) guided the minimalist statistical treatment of the data. We present variables one at a time to allow readers to readily evaluate the data and compare datasets. We have not used ordination or classification methods, nor have we calculated multivariate measures of association. Our hope is that readers will be stimulated by the data presented in this book to conduct additional analyses on their own using data available on the EcoTrends website.

The exploration of long-term trends in measurements and the consistency of such trends across a range of measurement variables, biomes, and geographic regions involve significant challenges because of the need to present several hundred time-based series of diverse variables measured at different intervals. Measurement methods vary greatly and have an array of different error structures. Accordingly, to explore temporal trends in a consistent manner across all variables in the space allowed, we rely principally on simple linear regression methods using $p \leq 0.05$ as our level of significance. Probability values for the significance of linear regressions have not been corrected for the effects of serial autocorrelation (Pyper and Peterman 1998).

We do not attempt to use alternative trend analysis or smoothing methods, either parametric or nonparametric, other than the calculation of a running mean for some variables. We test only for a linear relationship with time, although we are aware that some variables change in a nonlinear manner and higher order polynomials may be better descriptors of the underlying changes in certain datasets. In some cases, thresholds or relatively abrupt transitions may be apparent, but it was not practical to test for such responses across all variables. Again, we encourage readers to take the next steps on their own.

Organization of the Book

There are four main parts to this book. After a brief history (chapter 2), the first part consists of eight chapters (chapters 3-10) that illustrate the importance of long-term research across sites to address scientific questions or hypotheses. The research themes were selected based on their ecological importance and by the availability of long-term data for many sites, either previously published or in the EcoTrends database, that allow cross-site comparisons.

The second part consists of four chapters (chapters 11-14) that show long-term data and trends for each site. Each chapter contains a brief introduction to the topic and methods of measurements, selection of variables, and their data source. Each chapter consists primarily of a large number of figures showing long-term data for different variables. The figures are organized first by variable (for example, nitrogen), then by large-scale patterns in that variable across the country. For variables with many sites, we present the site-specific data through time for each ecosystem type. For variables with fewer than nine sites, we imbed the site graphs through time within a continental map to display broad-scale patterns in the variable.

The third part of this book consists of three chapters (chapters 15-17) containing management implications, recommendations for data accessibility in cross-site studies, and a synthesis of trends in the book followed by an identification of research needs.

The fourth part contains 28 appendices. Appendix 1 provides a short description of each site, and the other 27 appendices provide detailed information and summary statistics in a tabular format for each variable in chapters 11-14.

¹ Three-letter site codes used throughout this report; individual sites may use different acronyms.

² Program and agency abbreviations:

DOE: Department of Energy

LTER: Long Term Ecological Research Network

ARS: USDA Agricultural Research Service

USFS: USDA Forest Service

USGS: U.S. Geological Survey

U of A: University of Arizona

³ MAP: mean annual precipitation.

⁴ MAT: mean annual temperature.

⁵ Natural ecosystems near cities are shown in parentheses for the two urban sites. NTL is the only lake ecosystem currently in EcoTrends; this site is classified as eastern forest to allow cross-site comparisons. "Eastern forest" and "western forest" are used to indicate location of the site either east or west of the Mississippi River.

Table 1-2. Site classification by EcoTrends ecosystem type and World Wildlife Fund terrestrial biomes, using same color codes to denote ecosystem types as those used in figures in chapters 11-13

EcoTrends ecosystem type	World Wildlife Fund biome ¹	Site code
Alpine and arctic	Temperate coniferous forests Tundra	GLA, LVW, NWT ARC, MCM
Aridlands	Deserts and xeric shrublands	EOA, JRN, RCE, SEV, SRE, WGE
Coastal ²	Flooded grasslands and savannas Mediterranean forests, woodlands, and scrub Temperate broadleaf and mixed forests Temperate coniferous forests Tropical and subtropical moist broadleaf forests Tundra	FCE CCE, SBC PIE GCE, VCR MCR PAL
Eastern forests ³	Temperate broadleaf and mixed forests Temperate coniferous forests Tropical and subtropical moist broadleaf forests	BEN, CWT, FER, HBR, HFR, MAR, NTL ⁴ , TAL, WBW CRO, HAR, SAN LUQ
Temperate grasslands and savannas	Temperate broadleaf and mixed forests Temperate broadleaf and mixed forests/ Temperate grasslands, savannas, and shrublands Temperate grasslands, savannas, and shrublands	KBS ⁵ CDR FTK, GRL, GSW, KNZ, SGS, SPR
Urban ⁶	Deserts and xeric shrublands Temperate broadleaf and mixed forests/ Temperate coniferous forests	CAP BES
Western forests ³	Boreal forests/Taiga Temperate coniferous forests	BNZ AND, BLA, CHE, CSP, FRA, PRI, WIN

¹ <http://wwf.panda.org/>

² For coastal sites, terrestrial biomes are listed for the location of nearby land-based instrumentation (precipitation, temperature, precipitation chemistry).

³ Forests are separated into two groups (western, eastern forests) for ease of presentation based only on their geographic location relative to the Mississippi River.

⁴ NTL, a lake site, is classified here as eastern forest to allow cross-site comparisons.

⁵ KBS, an intensive row-crop ecosystem site, is classified here as temperate grasslands and savannas to allow cross-site comparisons.

⁶ For urban sites, the biomes of the surrounding natural ecosystems are given.
